With a graphical user interface (GUI) it is possible to build and manage computer models of power distribution systems (PDCS) and to solve math and physics problems. The PDCS models can be a standalone system that the user compiles themselves, or they can be made available online by the SimPowerPro server, which can then be downloaded to the user's computer. PDCS models can be defined in either a geographical or a 3D Cartesian environment. As opposed to 2D geographical models, 3D Cartesian models require a 3D environment for simulation of all electrical equipment (wires, transformers, switches, etc.). The development of new PDCS models and the importing and exporting of existing ones are performed through the graphical, point and click interface. These developments can be done on a personal computer, with as little as a text editor and the SimPowerPro GUI, and can be shared online for any future PDCS models. PDCS analysis techniques [8sec1] ===== SimPowerPro provides a full set of mathematical, electromechanical, and safety analysis techniques. The mathematical and electromechanical analysis techniques are used to solve for the current, voltage, or power distributions within the model. Using SimPowerPro's safety analysis, the user can create a criterion that an event must pass in order to perform a simulation. For example, a criterion that the magnitude of the current at any point must be less than a specific amount can be created, thereby guaranteeing the safety of electrical equipment in the model. In contrast, a criterion that the current must exceed a specific value at all points within the model ensures that the model is a functional representation of the real PDCS. Current and voltage analysis can be performed at several different levels within the model. Local, or point, current analysis is useful in analysis of points of interest. Point current analysis can be performed on individual branches of the model, and is generally the most useful when visualizing the model. For point current analysis, the user can set a series of points on the model and the software will calculate the values of current at each point. Point current analysis is also available for the overall circuit current and potential. In order to perform the analysis, the user selects a branch from which to calculate the circuit current and sets a series of points on the model. The program will then calculate the values of current at each point and display the results in a graph. In addition to the circuit current, the user can also calculate 82157476af
